1.1- Interaction with electromagnetic radiation

The coupling term between charged particles and the electromagnetic field, $\vec{p}_i \cdot \vec{A}(\vec{k} \cdot \vec{x} - wt)^1$, can be expressed through an expansion in $\vec{k} \cdot \vec{x}$ as $H_{\text{int}} = H_{\text{d}} + H_{\text{M}} + H_{\text{Q}}$ (see Shu I,24), for which

$$H_{\text{d}} = -\vec{E} \cdot \vec{d} \text{ (zeroth order)}$$

where, for a molecule, $\vec{d} = \vec{d}_{\text{el}} + \vec{d}_{\text{nuc}}$.

$$H_{\text{M}} = -\vec{B} \cdot \vec{M} \text{ (first order)}$$

where the magnetic dipole moment $\vec{M} \propto \vec{L}$, and

$$H_{\text{Q}} = -\frac{e}{6} \vec{\nabla} \vec{E} : (3\vec{x}\vec{x} - |\vec{x}|^2 \mathbb{I}) \text{ (also order one).}$$

In general $H_{\text{M}} > H_{\text{Q}}$.

¹when substituting $\vec{p} \rightarrow \vec{p} - \frac{q}{c} \vec{A}$, and neglecting terms in A^2 (OK for the ISM) see Shu I, 21

1.2- Bound-bound transition probabilities and cross-sections

In time-dependent perturbation theory, the rate of radiative excitations $i \rightarrow f$ is (Fermi's golden rule):

$$\frac{dP_{if}}{dt} \propto \Re(\omega_{if}) |\langle \phi_f | H_{\text{int}}(\omega) | \phi_i \rangle|^2.$$

In a cubic box where the occupation number of state \vec{n} is \Re , the density of states is $d^3\vec{n} = V d^3\omega / (2\pi c)^3$, with a volume $V \rightarrow \infty$. The absorption cross-section σ_{if} derives from $P_{if} = N_f / N_i \propto \#$ of absorbed photons ²:

$$P_{if} = \int d^3\vec{n} \frac{\Re(\vec{n})}{V} c t \sigma_{if} \Rightarrow \frac{dP_{if}}{dt} = \int_0^\infty \sigma_{if} c \Re(\omega) \frac{4\pi\omega^2}{(2\pi)^3 c^2} d\omega$$

Identifying (see Shu I, 22, 23), we obtain

$$\sigma_{if} \propto |\langle \phi_f | H_{\text{int}}(\omega) | \phi_i \rangle|^2 \delta(\omega - \omega_{if}).$$

1.3- Oscillator strength

For the electric dipole Hamiltonian, one gets

$$\sigma_{if} = \frac{4\pi^2}{3\hbar c} \left| \langle \phi_f | \vec{d} | \phi_i \rangle \right|^2 \delta(\omega - \omega_{if}),$$

which is usually expressed in terms of the oscillator strength f_{if} ,

$$\sigma_{if} = \frac{\pi e^2}{m_e c} f_{if} \delta(\nu - \nu_{if}), \quad \text{with} \quad f_{if} \equiv \frac{4\pi m_e}{3e^2 \hbar} \nu_{if} \left| \langle \phi_f | \vec{d} | \phi_i \rangle \right|^2.$$

For a single electron with position \vec{x} ,

$$f_{if} = \frac{2m_e(\omega_{if} \langle f | \vec{x} | i \rangle)^2}{3\hbar \omega_{if}},$$

which is roughly the ratio between the vibrational potential energy of the electron and that of the radiated photon.

1.4- Relationship with Einstein coefficients

The equation of detailed balance,

$$n_i B_{if} J_{\nu_{if}} = n_f A_{fi} + n_f B_{fi} J_{\nu_{fi}},$$

and the LTE relationships,

$$\frac{n_f}{n_i} = \frac{g_f}{g_i} \exp\left(-\frac{h\nu_{if}}{kT}\right), \quad \text{and} \quad J_\nu = B_\nu(T), \quad \text{lead to}$$

$$A_{fi} = \frac{g_i}{g_f} (2h\nu^3 / c^2) B_{if}, \quad B_{fi} = \frac{c^2}{2h\nu^3} A_{fi} = (g_i / g_f) B_{if}.$$

1.4- Relationship with Einstein coefficients

- The rate of stimulated excitations is related to the oscillator strength using the requirement

$$n_i B_{if} J_{\nu if} = \int d\nu \int d\Omega \sigma_{if} n_i \frac{J_{\nu}}{h\nu} = \int d\nu 4\pi \sigma_{if} n_i \frac{J_{\nu}}{h\nu} \quad (1)$$

- Therefore,

$$B_{if} = \frac{4\pi^2}{h\nu} \frac{e^2}{m_e c} f_{if}. \quad (2)$$

1.5- Natural line width

- We consider an atom in state i , subjected to radiation with frequency ω_{ji} , corresponding to the energy interval with a final state f .
- The wave function of the target can be expanded as

$$|\phi\rangle = \sum_j c_j |\phi_j\rangle. \quad (3)$$

- Denoting $\Gamma = A_{ji}$, the probability amplitude for state f satisfies

$$\frac{d|c_f|^2}{dt} = -\Gamma |c_f|^2. \quad (4)$$

- In terms of the amplitude coefficients, Fermi's golden rule should be modified to account for spontaneous decay:

$$\dot{c}_f = -i\hbar^{-1} \langle \phi_f | H_\alpha^{\text{abs}} | \phi_i \rangle e^{i(\omega_f - \omega)t} - \frac{\Gamma}{2} c_f. \quad (5)$$

- We can solve Eq. 5 recognizing $e^{\Gamma t/2}$ as an integrating factor.
- After taking the modulus, in the limit $t \rightarrow \infty$,

$$|c_f(\infty)|^2 = \hbar^{-2} \frac{|\langle \phi_f | H_\alpha^{\text{abs}} | \phi_i \rangle|^2}{(\omega_{fi} - \omega)^2 + (\Gamma/2)^2}. \quad (6)$$

- Electric dipole

- atoms: $\Delta l = 1, \Delta m = 0$.
- molecules:
 - vibrational-rotational transitions, or rovibrational, $\Delta J = \pm 1$, $\Delta m = 0, \Delta v = \pm 1$, allowed when $\Lambda \neq 0$, $\Delta J = 0^3$.
 - electronic transitions, $\Delta \Lambda = 0, \pm 1, \Delta S = 0$
 - electronic-vibrational-rotational transitions (i.e. *vibronic* transitions): $\Delta J = 0, \pm 1$, $\Delta m = 0, \pm 1$ and $\Delta J \neq 0$ if $\Lambda = \Delta \Lambda = 0$ and if $J = 0$.

$$\Delta J = \begin{cases} +1 \rightarrow \text{R branch} \\ 0 \rightarrow \text{Q branch} \\ -1 \rightarrow \text{P branch} \end{cases}$$

- magnetic dipole, atoms: $\Delta l = 0, \Delta m = 0, \pm 1$.
- electric quadrupole, atoms: $\Delta l = 0, \pm 2, \Delta m = 0, \pm 1, \pm 2$, rotational transitions in molecules $\Delta J = 0, \pm 1, \pm 2$.

1.7- Selection rules – H_2

- In the case of H_2 we have $\vec{d} = 0$. Moreover the fundamental state is $\vec{L} = 0$, and $\vec{S} = 0$, so that $\vec{M} = 0$ and all low-energy transitions for H_2 are quadrupolar.
- Note that the antisymmetry of the nuclear wave function implies that the state $J = 1$ (J odd) is triplet (**Ortho** H_2 , $I = S_{\text{nuclear}} = 1$), while $J = 0$ (J even) is singlet (**Para** H_2 , $I = 0$).
- In H_2 the exclusion principle⁴ forbids $\Delta J = 1$, unless the transition involves a change in spin state. The spin transitions can only occur through the exchange of protons in collisions. Radiative transitions between spin states can occur, but at a rate corresponding to the quadrupolar transitions in the Hamiltonian of the deviations to the Born-Oppenheimer approximations.

⁴the requirement that the wave function be antisymmetric

1.7- Selection rules – H₂

- In the ISM, **Ortho** and **Para** H₂ are effectively different molecules. The distinction extends to all molecules that contain H₂ radicals.
- Rovibrational transitions between an upper level ¹ and a lower level ² are written $(\nu_1 - \nu_2)O(J_2)$ when $J_2 - J_1 = -2$, $(\nu_1 - \nu_2)Q(J_2)$ when $J_2 - J_1 = 0$, $(\nu_1 - \nu_2)S(J_2)$ when $J_2 - J_1 = +2$.

Photoionization

Radiative recombination

2.1- Photoionization

In time-dependent perturbation theory, the rate of transition between two states, $i \rightarrow f$, is:

$$\frac{dP_{if}}{dt} = \frac{e^2}{hc^3 m_e^2} \sum_{\alpha=1}^2 \int \omega_{fi} \mathcal{N}_{\alpha}(\vec{k}) |\langle \phi_f | e^{i\vec{k} \cdot \vec{x}} \vec{e}_{\alpha} \cdot \vec{p} | \phi_i \rangle|^2 d\Omega,$$

where $\mathcal{N}(\vec{k})$ is the occupation number of photons in the state corresponding to \vec{k} , with frequency ν_{fi} .

In a photoionization process the final states f belong to the continuum. The Born approximation neglects the influence of the ion on $|\phi_f\rangle$, and for a description of the continuum we adopt a hard box normalization, with a size $L \rightarrow \infty$. With i corresponding to the fundamental state of the hydrogen atom, direct integration yields (Shu I, 23):

$$\frac{dP_{if}}{dt} = \frac{8\pi e^2 a_Z^3}{3V \hbar m_e^2 c^3} \mathcal{N}(\omega) (\hbar k_e)^2 \left(\frac{\hbar}{m_e a_Z^2} \right)^4, \quad (7)$$

where $\mathcal{N}(\omega) = \int d\Omega \mathcal{N}(\vec{\omega})$.

Photoionization and radiative recombination

Photoionization

Radiative recombination

2.1- Photoionization

The rate of absorption of ionizing photons with frequencies in the range $[\nu, \nu + \nu]$ is $dN_f \frac{dP_{if}}{dt}$, where dN_f is the number of free states in the corresponding range of energies,

$$dN_f = \frac{V}{2\pi^3} 4\pi k_e^2 dk_e,$$

where \vec{k}_e refers to the free electron. Conservation of energy, $E_f = \hbar\omega - E_i$, and $\hbar k_e = \sqrt{2M_e E_f}$, yield $k_e dk_e = \frac{m_e}{\hbar} d\omega$.

The cross-section of ionization is defined through

$$P_{if} dN_f = t \sigma_{if}(\omega) c \frac{\mathcal{N}(\vec{n})}{V} 4\pi n^2 dn, \text{ with } \frac{d^3 \vec{n}}{V} = \frac{d^3 \omega}{(2\pi)^3 c^3}. \quad (8)$$

2.1- Photoionization

Comparing Eq. 8 and Eq. 7 allows the identification of $\sigma(\nu)$:

$$\sigma(\nu) \propto \nu^{-3} g(\nu),$$

where $g(\nu)$ is a Gaunt factor, $g(\nu) \propto \nu^{-1/2}$, in the Born approximation, which is valid far from the ionization edge ν_o . $g_\nu \approx 1$ in the vicinity of ν_o , where the free-particle approximation breaks down.

Radiative recombination

2.2- Radiative recombination

Photoionization and its inverse process, radiative recombination, are related by the Einstein - Milne relations (e.g. Osterbrock, A1; Shu I,75; Spitzer p104). The detailed balance between photon absorptions with frequency ν and electron-ion recombinations with relative velocity v is

$$n_X a_\nu 4\pi \frac{B_\nu}{h\nu} d\nu = n_{X^+} n_e v \sigma(v) f(v) dv + n_{X^+} n_e \sigma_2(v) B_\nu v f(v) dv,$$

where $\frac{1}{2}mv^2 + h\nu_T = h\nu$, and where $f(v)$ is the Maxwellian integrated over angles. We get (taread) that $\sigma_2 = \sigma/(2h\nu^3/c^2)$, and

$$\sigma(v) = \frac{g}{g_+} \frac{h^2 \nu^2}{m^2 c^2 v^2} a_\nu,$$

where g and g_+ are the degeneracies of X and X^+ in their fundamental levels.
